The program project encompasses studies on the pharmacology, toxicology and therapeutic uses of these antibiotics. The research proposed for the next year is: 1) to study the structure and function of erythromycin binding proteins in pig gastric mucosa by high resolution binding studies, 2) to study the molecular basis for binding of erythromycin, clarithromycin, and azithromycin to the adenine nucleotide translocase of mammalian cells and the impact of these antibiotics on the function of this enzyme in mitochondrial transport, 3) to study the chemistry and pharmacology of azithromycin binding to rat liver mitochondrial ribosomes, and 4) to develop a selective and potent binding protein for azithromycin in bacteria.The term "paintball" refers to a paintball game in which teams of opposing players shoot paintballs at each other over a defined playing area. The game has enjoyed a relatively long period of popularity, including throughout Europe and the Americas. The paintballs used in the paintball game have a tendency to spread over a large area as they travel from the gun of a shooting player to the target area of a player who is being shot at. Once the paintballs land on a surface, the paint on the paintball typically becomes dry, and therefore makes it somewhat difficult to remove the paintball from the surface by using fingers, tweezers, or other types of pincer-like tools. A number of patents have issued in the past that are directed to paintball cleaning devices. For example, U.S. Pat. No. 4,507,755 issued to Davis on Apr. 2, 1985. In this patent, the patentee discloses an apparatus for cleaning or stripping of paint from the paintball after it has been shot from a paintball gun. This apparatus includes a paintball pouch containing a quantity of water, and a holder for securing the paintball pouch and including a mechanism for controlling the flow of water from the pouch. U.S. Pat. No. 5,845,091 issued 82157476af
